

A. Typical external control

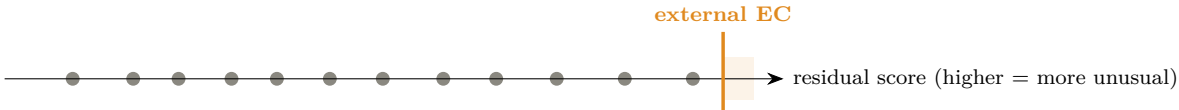

⇒ many controls rank above it ⇒ **keep**

6 of 12 randomized controls rank at least as high ⇒ $p = \frac{1+6}{12+1} = 0.54$

B. Extreme external control

⇒ almost none rank above it ⇒ **drop**

0 of 12 rank as high ⇒ $p = \frac{1+0}{12+1} = 0.08 \leq \gamma \Rightarrow$ screen out

the fitted model supplies the ordering; the randomized controls supply how extreme that ordering is
